

# NP Completeness

NP-completeness was introduced by **Stephen Cook** in 1971 in a foundational paper.

**Leonid Levin** independently introduced the same concept and proved that a variant of SAT is NP-complete.

6. On Relativization

# NP-Completeness

Gödel proved (1931): Theorem Proving is undecidable.

Gödel questioned (1956): What happens if we are only interested in theorems with short proofs?

From now on “polynomial time” is abbreviated to “P-time”.

## On the Definition of **NP**

**Theorem.** A language  $L \subseteq \{0, 1\}^*$  is in **NP** if and only if there exists a polynomial  $p : \mathbf{N} \rightarrow \mathbf{N}$  and a P-time TM  $\mathbb{M}$ , called a **verifier** for  $L$ , such that for every  $x \in \{0, 1\}^*$ ,

$$x \in L \text{ iff } \exists u \in \{0, 1\}^{p(|x|)}. \mathbb{M}(x, u) = 1.$$

If  $x \in L$  and  $u \in \{0, 1\}^{p(|x|)}$  satisfy  $\mathbb{M}(x, u) = 1$ , then we call  $u$  a **certificate** for  $x$  with respect to  $L$  and  $\mathbb{M}$ .

---

A sequence of successful choices can be seen as a certificate. Conversely a certificate can be generated nondeterministically.

# NP and Efficient Verifiability

**P**: The class of efficiently **solvable** problems.

**NP**: The class of efficiently **verifiable** problems.

---

- ▶ A problem in **P** will be called a P-problem.
- ▶ A problem in **NP** will be called an NP-problem.

# NP-Problems

1. IndSet, TSP, Subset Sum, 0/1 IntProg, dHamPath
2. Graph Isomorphism, Factoring
  - ▶ Babai's result in 2015,  $2^{\text{polylog}}$ .
  - ▶ Prime Factoring is NP-complete.
3. Linear Programming, Primalty

One can **reduce** one problem to another without even knowing any solutions to either.

# Karp Reduction

Suppose  $L, L' \subseteq \{0, 1\}^*$ .

We say that  $L$  is **Karp reducible** to  $L'$ , denoted by  $L \leq_K L'$ , if there is a P-time computable function  $r : \{0, 1\}^* \rightarrow \{0, 1\}^*$  such that for every  $x \in \{0, 1\}^*$ ,

$$x \in L \text{ iff } r(x) \in L'.$$

---

If  $L \leq_K L' \leq_K L''$  then  $L \leq_K L''$ .

# Hardness and Completeness

We say that  $L'$  is **NP-hard** if  $L \leq_K L'$  for every  $L \in \mathbf{NP}$ .

We say that  $L'$  is **NP-complete** if  $L'$  is NP-hard and  $L' \in \mathbf{NP}$ .

---

## Fact.

1. If language  $L$  is NP-hard and  $L \in \mathbf{P}$ , then  $\mathbf{P} = \mathbf{NP}$ .
2. If language  $L$  is NP-complete, then  $L \in \mathbf{P}$  iff  $\mathbf{P} = \mathbf{NP}$ .

Does there exist an NP-complete problem any way?

# Bounded Halting Problem

**Theorem.** The following language is NP-complete:

$$\text{TMSAT} \stackrel{\text{def}}{=} \{ \langle \alpha, x, 1^n, 1^t \rangle \mid \exists u \in \{0, 1\}^n. \mathbb{M}_\alpha(x, u) \text{ outputs } 1 \text{ in } t \text{ steps} \}.$$

---

Let  $L \in \mathbf{NP}$  be decided by a  $q$ -time TM  $\mathbb{M}$  using  $p$ -size certificate. Then “ $x \in L$ ” iff

$$\exists u \in \{0, 1\}^{p(|x|)}. \mathbb{M}(x, u) \text{ outputs } 1 \text{ in } q(|x| + p(|x|)) \text{ steps}$$

iff “ $\langle \perp \mathbb{M} \perp, x, 1^{p(|x|)}, 1^{q(|x| + p(|x|))} \rangle \in \text{TMSAT}$ ”.

---

The Karp reduction maps  $x$  onto  $\langle \perp \mathbb{M} \perp, x, 1^{p(|x|)}, 1^{q(|x| + p(|x|))} \rangle$ .

A language  $L \subseteq \{0, 1\}^*$  is in **coNP**  $\stackrel{\text{def}}{=} \{L \mid \bar{L} \in \mathbf{NP}\}$  if there exists a polynomial  $p : \mathbf{N} \rightarrow \mathbf{N}$  and a P-time TM  $\mathbb{M}$  such that

$$x \in L \text{ iff } \forall u \in \{0, 1\}^{p(|x|)}. \mathbb{M}(x, u) = 1$$

for every  $x$ .

---

$$\mathbf{P} \subseteq \mathbf{coNP} \cap \mathbf{NP}.$$

**P = NP** Implies **coNP = NP**.

**Theorem.** If  $\mathbf{P} = \mathbf{NP}$  then  $\mathbf{EXP} = \mathbf{NEXP}$ .

**Proof.**

Suppose  $L \in \mathbf{NEXP}$  is accepted by an NDTM in  $2^{n^c}$  time. Then

$$L_{\text{pad}} = \left\{ x01^{2^{|x|^c}} \mid x \in L \right\} \in \mathbf{NP}.$$

By assumption  $L_{\text{pad}} \in \mathbf{P}$ . But then  $L \in \mathbf{EXP}$ . □

The **padding** technique used in this proof was introduced by Berman and Hartmanis.

- 
1. Berman and Hartmanis. On Isomorphisms and Density of NP and Other Complete Sets. STOC, 1976.

# Cook-Levin Theorem

# Conjunctive Normal Form

A CNF formula has the form

$$\bigwedge_i \left( \bigvee_j v_{ij} \right),$$

where  $v_{ij}$  is called a **literal**, and  $\bigvee_j v_{ij}$  a **clause**. A literal is either a propositional variable, or the negation of a propositional variable.

---

A **k**CNF formula is a CNF formula in which all clauses contain at most  $k$  literals.

# The First Natural **NP**-Complete Problem

**SAT** is the language of all satisfiable CNF formulae.

---

- ▶ The set of the unsatisfiable DNF's is the complement of SAT.
- ▶ The set of the satisfiable DNF's is in **P**.

**Fact.**  $2SAT \in \mathbf{P}$ .

---

$x \vee \bar{y}$  for example is understood as both an edge from  $\bar{x}$  to  $\bar{y}$  and an edge from  $y$  to  $x$ .  
A  $2SAT \in \mathbf{P}$  formula  $\varphi$  is unsatisfiable if and only if there is some  $z$  such that  $\bar{z}$  is reachable from  $z$ .

# 3SAT

**Fact.**  $\text{SAT} \leq_K \text{3SAT}$ .

**Proof.**

For example  $u_1 \vee u_2 \vee u_3 \vee u_4 \vee u_5$  is satisfiable iff

$$(u_1 \vee u_2 \vee v) \wedge (\neg v \vee u_3 \vee w) \wedge (\neg w \vee u_4 \vee u_5)$$

is satisfiable. □

---

**Corollary.** 3SAT is NP-complete if SAT is NP-complete.

# Cook-Levin Theorem

**Theorem** (Cook, 1971; Levin, 1973). SAT is NP-complete.

# Variable Equality

Intuitively the formula

$$(x_1 \vee \overline{y_1}) \wedge (\overline{x_1} \vee y_1) \wedge \dots \wedge (x_n \vee \overline{y_n}) \wedge (\overline{x_n} \vee y_n)$$

is equivalent to

$$(x_1 = y_1) \wedge \dots \wedge (x_n = y_n).$$

## Formula Defining a Boolean Function

**Claim.** For every Boolean function  $f : \{0, 1\}^\ell \rightarrow \{0, 1\}$ , there is an  $\ell$ -variable CNF formula  $\varphi_f$  of size  $\ell 2^\ell$  such that  $\varphi_f(u) = f(u)$  for every  $u \in \{0, 1\}^\ell$ , where the size of a CNF formula is defined to be the number of  $\vee/\wedge$  symbols.

---

Let  $\varphi_f$  be

$$\bigwedge_{v \in \{0, 1\}^\ell \wedge f(v) = 0} C_v(z_1, \dots, z_\ell)$$

where for each  $v$ ,  $C_v(v) = 0$  and  $C_v(u) = 1$  for every  $u \neq v$ .

# Proof of Cook-Levin Theorem

Suppose  $L \in \mathbf{NP}$ . Let  $\mathbb{M}$  be a P-time TM and  $p$  a polynomial such that for every  $x \in \{0, 1\}^*$ ,  $x \in L$  iff  $\exists u \in \{0, 1\}^{p(|x|)}.\mathbb{M}(x, u) = 1$ .

Wlog, we may assume that  $\mathbb{M}$  is oblivious.

---

We shall construct a P-time computable function  $\varphi_- : L \rightarrow \text{SAT}$  such that “ $\varphi_x \in \text{SAT}$  iff  $x \in L$ ”, which is equivalent to saying that

$$\varphi_x \in \text{SAT} \text{ iff } \exists u \in \{0, 1\}^{p(|x|)}.\mathbb{M}(x \circ u) = 1.$$

# Proof of Cook-Levin Theorem

The idea is that  $\varphi_x$  should be a CNF formula such that

- ▶ it **reflects** the execution sequence of  $\mathbb{M}(x \circ u)$  from the initial configuration to the final configuration, and
- ▶  $\mathbb{M}(x \circ u) = 1$  iff the CNF formula is satisfiable.

# Proof of Cook-Levin Theorem

We choose to encode snapshots rather than configurations.

- ▶ “Computation is local.”

---

The  $i$ -th snapshot  $z_i$  depends only on  $z_{i-1}$ ,  $\text{prev}(i)$ ,  $\text{inputpos}(i)$ .

- ▶ The current state is calculated from  $z_{i-1}$ .
- ▶ The symbol at the input tape is read at  $\text{inputpos}(i)$ .
- ▶ The other symbols are collected from  $\text{prev}(i)$ 's.

# Proof of Cook-Levin Theorem

Now  $x \in L$  if and only if

$$\exists y \in \{0, 1\}^{|x|+p(|x|)}. \exists z_1 \dots z_{T(|x|)}. \varphi_x(y, z_1, \dots, z_{T(|x|)})$$

where  $\varphi_x(y, z_1, \dots, z_{T(|x|)})$  is the conjunction of the following propositions.

1.  $x$  is a prefix of  $y$ ;
2.  $z_1$  encodes the initial snapshot;
3.  $z_{T(|x|)}$  encodes the final snapshot with output 1;
4.  $z_{\text{prev}(i)}, z_{i-1}, z_i$  and  $y_{\text{inputpos}(i)}$  must satisfy the relationship imposed by the transition function.

---

The size of  $z_i$  is bounded by  $(3c + \log n)2^{3c + \log n}$ , where  $c$  is the size of snapshot.  
Conclude that  $\varphi_x(y, \tilde{z})$  is of polynomial length.

# Proof of Cook-Levin Theorem

$\varphi_x(y, \tilde{z})$  is constructed in P-time.

---

- ▶ Calculate  $|x \circ u|$  in P-time, and
- ▶ Simulate  $\mathbb{M}$  on  $0^{|x \circ u|}$  in P-time to calculate
  - ▶ the head positions at the  $i$ -th step, and
  - ▶ for each work tape the largest  $j < i$  such that at the  $j$ -th step the head of the work tape was scanning the same cell as it is scanning at the  $i$ -th step.

# Property of Cook-Levin Reduction

The reduction is a **Levin reduction**.

- ▶ A reduction from an NP language to another is a Levin reduction if it provides an efficient method to transform certificates to certificates forward and backward.

The reduction is **parsimonious**.

- ▶ A reduction  $r$  from an NP language to another NP language is parsimonious if the number of the certificates of  $x$  is equal to the number of the certificates of  $r(x)$ .

The reduction can be done in **logspace**.

- ▶ Logspace reduction will be defined in a later lecture. Confer Papadimitriou's book.

## Decision vs. Search

Search problems are evidently harder than the corresponding decision problems. They are however equivalent in some sense.

---

**Theorem.** If  $\mathbf{P} = \mathbf{NP}$ , then for every  $\mathbf{NP}$  language  $L$ , there is a P-time TM that on input  $x \in L$  outputs a certificate for  $x$ .

**Proof.**

Construct a Levin reduction from  $L \in \mathbf{NP}$  to SAT.

Given a CNF formula with  $n$  variables, we can call upon a P-time algorithm for SAT for  $n + 1$  times to find a certificate for the formula if it is satisfiable. We then apply the Levin reduction to get a certificate for  $x$ . □

**Theorem.** The following language is co-NP-complete:

$$\text{TAUTOLOGY} = \{\varphi \mid \varphi \text{ is a tautology}\}.$$

---

$$“L \in \mathbf{coNP}” \Rightarrow “\bar{L} \in \mathbf{NP}” \Rightarrow “\bar{L} \leq_K \text{SAT}” \Rightarrow “L \leq_K \overline{\text{SAT}}”.$$

# Karp Theorem

Soon after Cook's paper, Richard Karp showed in 1972 that 21 combinatorial problems are NP-complete.

- 
1. Reducibility Among Combinatorial Problems. In Complexity of Computer Computations, R. Miller and J. Thatcher (editors), 85-103, 1972.

# Karp's 21 NP-Complete Problems

## SAT

# Gödel's Question Answered

Let  $\mathcal{A}$  be a familiar axiomatic system. Let **THEOREM** be the problem

$$\left\{ (\varphi, 1^{|\varphi|^c}) \mid \varphi \text{ has a formal proof of length } \leq |\varphi|^c \text{ in } \mathcal{A} \right\}.$$

This is the finite version of Hilbert's problem.

---

**Fact.** **THEOREM** is NP-complete.

**Proof.**

1. In familiar axiomatic systems, such as PA and ZF, verification runs in time polynomial in the length of proof.
2. A propositional tautology has a polynomial size proof. □

Gödel essentially raised the question “ $\mathbf{P} \stackrel{?}{=} \mathbf{NP}$ ” as early as in 1956 in a private communication to John von Neumann.

# Berman-Hartmanis Conjecture

**Conjecture.** NP-complete problems are polynomially isomorphic.

---

Evidence:

- ▶  $A \leq_K^1 B$  for all known NP-complete problems  $A, B$ .
- ▶ If  $A \leq_K^1 B \leq_K^1 A$  then  $A \cong_p B$ .

The proof is similar to that of Myhill Isomorphism Theorem.

# Berman-Hartmanis Conjecture

**Fact.** Berman-Hartmanis Conjecture implies  $\mathbf{P} \neq \mathbf{NP}$ .

---

A dense language cannot be  $p$ -isomorphic to a sparse language.

- ▶ SAT is dense.
  - ▶  $\{1^n \mid n \in \mathbf{N}\}$  is sparse.
- 

A set  $S \subseteq \{0, 1\}^*$  is dense if  $|S^{\leq n}| = 2^{n^{O(1)}}$ ; it is sparse if  $|S^{\leq n}| = n^{O(1)}$ .

# Ladner Theorem

We have seen many NP-complete problems.

Is there an NP-problem that is neither in **P** nor NP-complete?

---

Finding such a problem is at least as hard as proving "**P**  $\neq$  **NP**".

**Ladner Theorem.** If  $\mathbf{P} \neq \mathbf{NP}$ , then there is a language neither in  $\mathbf{P}$  nor NP-complete.

---

1. Richard Ladner. On the Structure of Polynomial Time Reducibility. J. ACM, 1975.

# Motivation

We know that SAT is NP-complete whereas 2SAT is in **P**.

The idea is to remove from SAT just enough instances so that the remaining set is not NP-complete, but not enough to make it in **P**.

---

Technically think of  $\psi 01^n$  as  $\psi \wedge v_1 \wedge \dots \wedge v_n$ . Observe that

- ▶  $\{\psi 01^{|\psi|^c} \mid \psi \in \text{SAT}\}$  is NP-complete, whereas
- ▶  $\{\psi 01^{2^{|\psi|}} \mid \psi \in \text{SAT}\}$  is in **P**.

---

We will find some  $H(x)$  such that  $x^{H(x)}$  does the job.

The problem

$$\text{SAT}_H = \left\{ \psi 01^{|\psi|^{H(|\psi|)}} \mid \psi \in \text{SAT} \right\},$$

and the function

$$H(n) = \begin{cases} i, & i < \log \log n \text{ is the smallest index of a TM such that} \\ & \mathbb{M}_i(x) \text{ outputs } \text{SAT}_H(x) \text{ in } i|x|^i \text{ steps for all } x \text{ with } |x| \leq \log n. \\ \log \log n, & \text{otherwise.} \end{cases}$$

- 
1.  $\text{SAT}_H$  and  $H(n)$  are well defined.  $H(n)$  is nondecreasing since  $i < H(n) \Rightarrow i < H(n+1)$ .
  2.  $\text{SAT}_H \in \mathbf{NP}$  because  $H(n)$  is computable in  $o(n^3)$ -time. Confer

$$T(n) = (\log \log n) 2^{\log n} (c \cdot C \log C + 2^{\log n} + T(\log n) + \dots),$$

where  $C = (\log \log n)(\log n)^{\log \log n}$  and  $c = o(\log n)$ .

**Fact.** If  $H(\mathbf{N})$  is finite, then some  $\mathbb{M}_i$  decides  $\text{SAT}_H$  in  $in^i$ -steps.

**Proof.**

If  $H(\mathbf{N})$  is finite, then since  $H$  is nondecreasing, some  $i$  exists such that  $H(n) = i$  for all large  $n$ . But then  $\mathbb{M}_i$  decides  $\text{SAT}_H(x)$  in  $i|x|^i$  steps.  $\square$

---

**Fact.**  $\text{SAT}_H \in \mathbf{P}$  iff  $H(\mathbf{N})$  is finite.

**Proof.**

Suppose  $\mathbb{M}_i$  decides  $\text{SAT}_H$  in  $cn^c$ -steps for some  $c$ . Let  $i$  be such that  $i \geq c$ . Then  $H(n) \leq i$  for all large  $n$ .  $\square$

---

**Lemma.** If  $\mathbf{P} \neq \mathbf{NP}$  then  $\text{SAT}_H \notin \mathbf{P}$ .

**Proof.**

If  $\text{SAT}_H \in \mathbf{P}$ , then  $\text{SAT} \leq_K \text{SAT}_H$  by the above fact.  $\square$

**Lemma.** If  $\mathbf{P} \neq \mathbf{NP}$  then  $\text{SAT}_H$  is not NP-complete.

---

Assume that  $\text{SAT}_H$  was NP-complete.

- ▶ There would be some  $in^i$  time Karp reduction  $r : \text{SAT} \rightarrow \text{SAT}_H$ .
  - ▶ Fix some  $N$  such that  $|r(\varphi)| = |\psi 01^{|\psi|^{H(|\psi|)}}| > N$  implies  $|\psi| < \sqrt{|\varphi|}$ .
- 

A P-time algorithm  $\text{Sat}(\varphi)$  for SAT is defined as follows:

1. Compute  $r(\varphi)$ , which must be  $\psi 01^{|\psi|^{H(|\psi|)}}$  for some  $\psi$ .
2. If  $|r(\varphi)| > N$ , call  $\text{Sat}(\psi)$  recursively, otherwise apply brutal force.

The depth of recursive call is bounded by  $\log \log |\varphi|$ .

Under plausible complexity theoretical assumptions, there are natural problems that are not NP-complete. However none of these problems has been shown to lie outside **P**.

# Baker-Gill-Solovay Theorem

Isn't it tempting to look for a very clever use of diagonalization to construct an intermediate language without assuming  $\mathbf{P} \neq \mathbf{NP}$ ?

Theodore Baker, John Gill and Robert Solovay published in 1975 a profound result that brought up the issue of relativization.

---

1. Relativizations of the  $P \stackrel{?}{=} NP$  Question. SIAM Journal on Computing, 4(4):431-442, 1975.

# Oracle Turing Machine

An **Oracle Turing Machine** (OTM) is a TM  $M^?$  that has additionally one read-write **oracle tape** and **states**  $q_{\text{query}}$ ,  $q_{\text{yes}}$ ,  $q_{\text{no}}$ .

- ▶ To execute  $M^?$  we need to specify an **oracle**  $B \subseteq \{0,1\}^*$ .
- ▶ During an execution whenever  $M^B$  enters the state  $q_{\text{query}}$ , the machine moves into the state  $q_{\text{yes}}$  if  $a \in B$  and  $q_{\text{no}}$  if  $a \notin B$ , where  $a$  is what is on the oracle tape.
- ▶ A query to  $B$  counts as a **single** computation step.

We write  $M^B(x)$  for the output of  $M^B$  on input  $x$ .

---

**Nondeterministic Oracle TM's** are defined similarly.

The Gödel encoding of the OTM's is independent of any oracle.

►  $M_0^?, M_1^?, M_2^?, \dots$

# $P^O$ and $NP^O$

Suppose  $O \subseteq \{0, 1\}^*$ .

- ▶  $P^O$  is the set of all languages decidable by P-time TM's with access to  $O$ .
- ▶  $NP^O$  is the set of all languages acceptable by P-time NDTM's with access to  $O$ .

---

$NP^{O[k]} \subseteq NP^O$ .

- ▶ The oracle can be queried for at most  $k$  times in any run.

The complexity class  $\mathbf{NP}^{\mathbf{NP}}$  for example is defined as follows:

$$\mathbf{NP}^{\mathbf{NP}} = \bigcup_{L \in \mathbf{NP}} \mathbf{NP}^L.$$

## Example

1.  $\overline{\text{SAT}} \in \mathbf{P}^{\text{SAT}}$ .
2.  $\mathbf{P}^A = \mathbf{P}$  if  $A \in \mathbf{P}$ .
3.  $\mathbf{NP}^{\mathbf{NP}} = \mathbf{NP}^{\text{SAT}}$ .

# Cook Reduction

A language  $L$  is **Cook reducible** to a language  $L'$  if there is a P-time OTM  $M^?$  such that  $L$  is decided by  $M^{L'}$ .

- ▶  $L$  is Cook reducible to  $L'$  iff  $L$  is Cook reducible to  $\overline{L'}$ .

# Meditation on Reduction

Historically,

- ▶ Cook used the P-time Turing reduction in the 1971 paper,
- ▶ Karp restricted to the P-time m-reduction in the 1972 paper,
- ▶ Levin defined reduction for search problems in the 1973 paper.

---

Why Karp reduction in the definition of NP-completeness? Why not Cook reduction?

- ▶ Completeness is better defined in terms of Cook reduction.
  - ▶ Yet all known NP-completeness results can be established using Karp reduction.
- ▶ **NP** = **coNP** if reductions are understood as Cook reductions.

# Lowness

A complexity class **B** is **low** for a complexity class **A** if  $\mathbf{A}^{\mathbf{B}} = \mathbf{A}$ .

- Problems in **B** are not only solvable, they are also easy to solve in **A**'s viewpoint.

# Lowness

If **A** is low for itself then **A** is closed under complement, provided it is powerful enough to negate boolean results.

- ▶ **P** is low for itself.
- ▶ **NP** is believed not to be low for itself.
- ▶ **PSPACE** is low for itself.
- ▶ **L** is low for itself.
- ▶ **EXP** is not low for itself, although  $\overline{\mathbf{EXP}} = \mathbf{EXP}$ .
  - ▶ An exponential time OTM can ask exponential size questions.

**Baker-Gill-Solovay Theorem.** There are  $A, B$  such that  $\mathbf{P}^A = \mathbf{NP}^A$  and  $\mathbf{P}^B \neq \mathbf{NP}^B$ .

# Proof of Baker-Gill-Solovay Theorem, Case A

Let  $A$  be the following language

$$\{\langle \alpha, x, 1^n \rangle \mid M_\alpha \text{ outputs } 1 \text{ on } x \text{ within } 2^n \text{ steps}\}.$$

Then  $\mathbf{EXP} \subseteq \mathbf{P}^A \subseteq \mathbf{NP}^A \subseteq \mathbf{EXP}$ . Hence  $\mathbf{P}^A = \mathbf{NP}^A$ .

# Proof of Baker-Gill-Solovay Theorem, Case B

Basic idea of oracle  $B$ :

- ▶ A machine that only makes a polynomial number of queries can never get it right for every input.
- ▶ A machine that makes an exponential number of queries can always make the right judgments for all inputs.

# Proof of Baker-Gill-Solovay Theorem, Case B

Let  $B_0 = \emptyset$  and  $n_0 = 0$ . Construct  $B_{i+1}$  from  $B_i$  as follows:

- ▶ Let  $n_{i+1}$  be larger than  $n_0, n_1, \dots, n_i$ .
  - ▶ Moreover  $n_{i+1}$  must be larger than the size of all strings that have been queried when constructing  $B_1, \dots, B_i$ .
- ▶ Run  $\mathbb{M}_i^{B_i}$  on  $1^{n_{i+1}}$  for  $2^{n_{i+1}-1}$  steps.
  - ▶ If  $\mathbb{M}_i^{B_i}(1^{n_{i+1}})$  does not stop in  $2^{n_{i+1}-1}$  steps, let  $B_{i+1} = B_i$ .
  - ▶ If  $\mathbb{M}_i^{B_i}$  accepts  $1^{n_{i+1}}$  in  $2^{n_{i+1}-1}$  steps, let  $B_{i+1} = B_i$ .
  - ▶ If  $\mathbb{M}_i^{B_i}$  rejects  $1^{n_{i+1}}$  in  $2^{n_{i+1}-1}$  steps, let  $B_{i+1} = B_i \cup \{s\}$ , where  $|s| = n_{i+1}$  and  $s$  is not queried when executing  $\mathbb{M}_i^{B_i}(1^{n_{i+1}})$ .

Let  $B = \bigcup_{i \in \mathbb{N}} B_i$ .

# Proof of Baker-Gill-Solovay Theorem, Case B

Let  $U_B$  be defined as follows:

$$U_B = \{1^n \mid B \text{ contains a string of length } n\}.$$

---

**Lemma.**  $U_B \in \mathbf{NP}^B$  and  $U_B \notin \mathbf{P}^B$ .

**Proof.**

Suppose  $\mathbb{M}_i^B$  decided  $U_B$  in P-time  $T(n)$ .

Choose a large enough  $i$  such that  $T(n_i) < 2^{n_i-1}$ .

By construction  $\mathbb{M}_i^B(1^{n_{i+1}}) = 1$  iff  $\mathbb{M}_i^B(1^{n_{i+1}}) = 0$ .  $[\mathbb{M}_i^B(1^{n_{i+1}}) = \mathbb{M}_i^{B_i}(1^{n_{i+1}})]$

# On Relativization

# Relativization

A proof of  $\mathbf{A} \neq \mathbf{B}$  ( $\mathbf{A} = \mathbf{B}$ ) **relativizes** if it is also essentially a proof of  $\mathbf{A}^O \neq \mathbf{B}^O$  ( $\mathbf{A}^O = \mathbf{B}^O$ ) without specifying the oracle  $O$ .

“We feel that this is further evidence of the difficulty of the  $\mathbf{P} \stackrel{?}{=} \mathbf{NP}$  question. . . .  
It seems unlikely that ordinary **diagonalization** methods are adequate for producing an example of a language in  $\mathbf{NP}$  but not in  $\mathbf{P}$ ; such diagonalizations, we would expect, would apply equally well to the relativized classes. . . .  
On the other hand, we do not feel that one can give a general method for **simulating** nondeterministic machines by deterministic machines in polynomial time, since such a method should apply as well to relativized machines.”

Baker, Gill, and Solovay

# Relativization Barrier

Whatever a proof of  $\mathbf{P} \neq \mathbf{NP}$  (or  $\mathbf{P} = \mathbf{NP}$ ) is, it cannot be a proof that relativizes. It seems to rule out any possibility of using diagonalization/simulation to settle the issue.

- ▶ This appears very surprising since Recursion Theory does relativize and Complexity Theory can be seen as a resource bounded version of Recursion Theory.

## Relativization Barrier in 1975-1988

Hopcroft (1984):

This perplexing state of affairs is obviously unsatisfactory as it stands. No problem that has been relativized in two conflicting ways has yet been solved, and this fact is generally taken as evidence that the solutions of such problems are beyond the current state of mathematics.

The researchers were not aware of a true complexity theoretical statement whose negation is also true in some relativized world.

- ▶ The general practice was either to prove something or to refute it in some relativized world.

# Relativization Barrier, Mystery or Myth

From early on researchers have noticed that separation by relativization often exploits difference of oracle access mechanisms.

- ▶ Baker-Gill-Solovay Theorem.
- ▶ Another example is Hopcroft, Paul and Valiant's result that  $\mathbf{TIME}(S(n)) \subsetneq \mathbf{SPACE}(S(n))$  for space constructible  $S(n)$ .
  - ▶ Hartmanis, Chang, Chari, Ranjan, and Rohatgi have come up with an oracle  $A$  such that  $\mathbf{TIME}^A(S(n)) = \mathbf{SPACE}^A(S(n))$ .
- ▶ Speedup Theorem.

“This example demonstrates the danger in thinking of oracle worlds as a way of relativizing complexity classes – oracles do not relativize complexity classes, they only relativize the machines.”

Hartmanis, Chang, Chari, Ranjan and Rohatgi, 1992.

We will see that some big proofs in complexity theory are non-relativizing.

$$P \stackrel{?}{=} NP$$

only time can tell.
